### 1 Semi-decidable vs. decidable

We know that a language may be semi-decidable but not decidable. However, if both  $L$  and its complement  $\bar{L}$  are semi-decidable then  $L$  must in fact be decidable.

**Claim 1.** *If a language  $L$  and its complement  $\bar{L}$  are both semi-decidable, then  $L$  is decidable.*

*Proof.* Let  $M_L$  be a TM accepting  $L$ , and let  $M_{\bar{L}}$  be a TM accepting  $\bar{L}$ . On input  $x$ , run both TMs “in parallel”, until one of them accepts. (At some finite point in time, one of the machines must accept as every input  $x$  is either in  $L$  or in  $\bar{L}$ .) If  $M_L$  accepted, then halt and accept. If  $M_{\bar{L}}$  accepted, then halt and reject.  $\square$

As a corollary, we get that the *complement* of  $A_{TM}$  is *not* semi-decidable! Do you see why?  
We also have the following.

**Theorem 1.** *The class of decidable languages is closed under complementation. On the other hand, the class of semi-decidable languages is not closed under complementation.*

*Proof.* Given a DTM  $M$  deciding a language  $L = L(M)$ , construct a new DTM  $M'$  by taking  $M$  and swapping  $q_{accept}$  and  $q_{reject}$  states. It's easy to see that the new DTM  $M'$  accepts exactly those strings that are rejected by  $M$ , and rejects exactly those strings that are accepted by  $M$ . So, we have  $L(M') = \bar{L}$ , as required.

On the other hand,  $A_{TM}$  is semi-decidable, but, as observed above, its complement is not semi-decidable.  $\square$

### 2 Examples of undecidable languages

**Theorem 2.** *The language*

$$E_{TM} = \{\langle M \rangle \mid L(M) \text{ is empty}\}$$

*is undecidable.*

*Proof.* Proof by reduction from  $A_{TM}$ . Given input  $\langle M, w \rangle$ , design a TM  $M'$  as follows:

$M'$ : “On input  $x$ , simulate  $M$  on input  $w$ . If  $M$  accepts, then Accept.”

Observe that

1. if  $M$  accepts  $w$ , then  $L(M') = \Sigma^*$  (i.e.,  $M'$  accepts every input  $x$ ),
2. if  $M$  does not accept  $w$ , then  $L(M') = \emptyset$ .

Now, if we have a decider TM  $R$  for the language  $E_{TM}$ , we can decide  $A_{TM}$  as follows:

“On input  $\langle M, w \rangle$ ,

1. Construct the TM  $M'$  for this pair  $\langle M, w \rangle$ , as explained above.
2. Run  $R$  on input  $\langle M' \rangle$ .
3. If  $R$  accepts  $\langle M' \rangle$ , then Reject. If  $R$  rejects  $\langle M' \rangle$ , then Accept.”

□

**Theorem 3.** *The language*

$$ALL_{TM} = \{\langle M \rangle \mid L(M) = \Sigma^*\}$$

*is undecidable.*

*Proof.* Suppose that  $ALL_{TM}$  is decidable by  $R$ . Show how to decide  $A_{TM}$ .

On input  $\langle M, w \rangle$ , construct TM  $M'$  as follows:

$M'$ : “On input  $x$ , simulate  $M$  on  $w$ , accepting if  $M$  accepts  $w$ ”.

Now, if  $M$  accepts  $w$ , then  $L(M') = \Sigma^*$ ; and if  $M$  does not accept  $w$ , then  $L(M') = \emptyset$ .  
So to decide  $A_{TM}$ , do the following:

“On input  $\langle M, w \rangle$ , construct TM  $M'$  defined above. Run  $R$  on input  $\langle M' \rangle$ . If  $R$  accepts  $\langle M' \rangle$ , then Accept; otherwise, Reject.”

Since  $A_{TM}$  is undecidable, we conclude that  $R$  cannot exist.

□

### 3 Another example of undecidability

**Theorem 4.** *The language*

$$EQ_{TM} = \{\langle M_1, M_2 \rangle \mid L(M_1) = L(M_2)\}$$

*is undecidable.*

*Proof.* Suppose it is decidable by some decider  $R$ . We reduce  $E_{TM}$  to  $EQ_{TM}$ .

Given  $\langle M \rangle$ , construct  $M_1 = M$  and  $M_2 = M_\emptyset$ , where  $M_\emptyset$  is some fixed TM such that  $L(M_\emptyset) = \emptyset$ . Clearly, we have  $L(M) = \emptyset$  iff  $L(M_1) = L(M_2)$ .

So, to decide  $E_{TM}$ , we do the following:

“On input  $\langle M \rangle$ , construct  $M_1$  and  $M_2$ , as described above. Run  $R$  on  $\langle M_1, M_2 \rangle$ . If  $R$  accepts, then Accept; otherwise, Reject.”

Since  $E_{TM}$  is undecidable (as shown above), we conclude that  $R$  cannot exist.

□

## 4 Rice's Theorem

Generalizing the arguments above, we will prove that essentially every nontrivial property of TM languages is undecidable. More precisely,

**Theorem 5** (Rice's theorem). *Any nontrivial property  $P$  of TMs is undecidable.*

Here a *property* is a collection of TM descriptions  $\langle M \rangle$  such that, for any two  $M_1$  and  $M_2$ , if  $L(M_1) = L(M_2)$  then either  $\langle M_1 \rangle, \langle M_2 \rangle \in P$ , or  $\langle M_1 \rangle, \langle M_2 \rangle \notin P$ .<sup>1</sup>

*Nontrivial* means that it is neither empty nor everything: some TM  $M_1$  exists such that  $\langle M_1 \rangle \in P$ , and some TM  $M_2$  exists such that  $\langle M_2 \rangle \notin P$ .

Before we do the proof, consider the language  $E_{TM} = \{\langle M \rangle \mid L(M) = \emptyset\}$ . Verify that  $E_{TM}$  satisfies the definition of a nontrivial property. Thus, Rice's theorem implies that  $E_{TM}$  is undecidable!

For an example of a non-property, consider the set of TM descriptions  $\langle M \rangle$  such that the length of the description  $|\langle M \rangle| > 100$ . This set is not a property in the above sense because we can have two TMs  $M_1$  and  $M_2$  with  $L(M_1) = L(M_2) = \emptyset$ , but  $|\langle M_1 \rangle| < 100$  while  $|\langle M_2 \rangle| > 100$ . Can you see how to design such  $M_1$  and  $M_2$ ?

*Proof of Rice's Theorem.* Towards a contradiction, suppose some nontrivial property  $P$  is decidable by  $R$ . We'll show how to decide  $A_{TM}$ .

Assume, without loss of generality, that  $\langle M_1 \rangle \in P$  for a TM  $M_1$  such that  $L(M_1) = \emptyset$ . Let  $M_2$  be any TM such that  $\langle M_2 \rangle \notin P$ . (Such  $M_2$  exists since  $P$  is nontrivial.)

Given an instance  $\langle M, w \rangle$  of  $A_{TM}$ , do the following:

1. Construct TM  $A$ :

$A$ : "On input  $x$ , run  $M$  on  $w$ . If  $M$  accepts  $w$ , then simulate  $M_2$  on  $x$ , accepting if  $M_2$  accepts."

2. Run  $R$  on input  $\langle A \rangle$ .
3. If  $R$  accepts  $\langle A \rangle$ , then Reject; If  $R$  rejects  $\langle A \rangle$ , then Accept.

Note on the construction of TM  $A$ :

- If  $M$  accepts  $w$ , then  $L(A) = L(M_2)$ , and so  $\langle A \rangle \notin P$  (since  $\langle M_2 \rangle \notin P$ ).
- If  $M$  does not accept  $w$ , then  $L(A) = L(M_1) = \emptyset$ , and so  $\langle A \rangle \in P$  (since  $\langle M_1 \rangle \in P$ ).

Thus, by being able to decide whether  $\langle A \rangle$  is in  $P$  or is not in  $P$ , we can decide whether  $M$  accepts  $w$ , or not. In other words, we can decide  $A_{TM}$ . A contradiction.  $\square$

**Justification of** "without loss of generality, can assume  $\langle M_1 \rangle \in P$ , with  $L(M_1) = \emptyset$ ":

Take some fixed  $M_1$  such that  $L(M_1) = \emptyset$ . Either  $\langle M_1 \rangle \in P$ , or  $\langle M_1 \rangle \notin P$ . If it is in  $P$ , then we're done. If  $\langle M_1 \rangle \notin P$ , then  $\langle M_1 \rangle \in \bar{P}$ , where  $\bar{P}$  is the complement of  $P$ . It's easy to see that  $\bar{P}$  is also a property if  $P$  is a property, and that  $\bar{P}$  is nontrivial if  $P$  is nontrivial. Then we argue about the property  $\bar{P}$  as before, reaching the conclusion that  $\bar{P}$  is undecidable. Since  $P$  is decidable iff its complement is decidable, we get that  $P$  is undecidable as well.

---

<sup>1</sup>One can define an *equivalence relation*  $\equiv$  on TM descriptions:  $\langle M_1 \rangle \equiv \langle M_2 \rangle$  iff  $L(M_1) = L(M_2)$ . Then a property  $P$  can be thought of as a collection of *equivalence classes* under the equivalence relation  $\equiv$ .

## 5 Reductions

We will consider a special kind of reductions: *mapping reductions*.

**Definition 1.** Language  $A$  is  $m$ -reducible to  $B$  (denoted  $A < B$ ) if there is a computable function  $f : \Sigma^* \rightarrow \Sigma^*$  such that, for every  $x \in \Sigma^*$ ,

$$x \in A \Leftrightarrow f(x) \in B.$$

**Theorem 6.** If  $A < B$ , and  $B$  is decidable, then so is  $A$ . If  $A < B$ , and  $B$  is semi-decidable, then so is  $A$ .

**The contrapositive:** If  $A < B$ , and  $A$  is not (semi-) decidable, then neither is  $B$ .

**Remark 1.** You can interpret “ $<$ ” as saying “less hard than”.

### 5.1 Examples

$E_{TM} < EQ_{TM}$  via the reduction  $f$  such that  $f(\langle M \rangle) = \langle M, M_0 \rangle$ , where  $M_0$  is some fixed TM such that  $L(M_0) = \emptyset$ . (Check that this is indeed a reduction!)

**Theorem 7.**  $EQ_{TM}$  is not semi-decidable.

*Proof.* We reduce the complement of  $A_{TM}$  to  $EQ_{TM}$ . Given  $\langle M, w \rangle$ , define  $f(\langle M, w \rangle) = \langle M_1, M_2 \rangle$  where

- $M_1$ : “On input  $x$ , simulate TM  $M$  on input  $w$ , accepting if  $M$  accepts”.
- $M_2 = M_0$  (where  $M_0$  accepts the empty language).

Note that  $L(M_1) = \Sigma^*$ , if  $M$  accepts  $w$ ; and  $L(M_1) = \emptyset$ , if  $M$  does not accept  $w$ . So this is indeed a reduction. Since we know that the complement of  $A_{TM}$  is not semi-decidable, we conclude that  $EQ_{TM}$  is not semi-decidable as well.  $\square$

## 6 Hardness of INF

Consider the language  $INF = \{\langle M \rangle \mid L(M) \text{ is infinite}\}$ .

We will prove the following:

1.  $INF$  is undecidable.
2.  $INF$  is not semi-decidable.
3. The complement of  $INF$  is not semi-decidable.

To prove  $INF$  is undecidable we can either refer to Rice’s theorem (arguing that  $INF$  is a non-trivial property), or give a direct reduction, e.g.,  $A_{TM} < INF$  as follows.

**Theorem 8.**  $A_{TM} < INF$ .

*Proof.* Given  $\langle M, w \rangle$ , construct  $M'$ : “On input  $x$ , simulate  $M$  on  $w$ . If  $M$  accepts  $w$ , then Accept.”

Clearly,  $M$  accepts  $w$  iff  $L(M') = \Sigma^*$  is infinite. (If  $M$  does not accept  $w$ , then  $L(M') = \emptyset$ .)  $\square$

To prove  $INF$  is not semi-decidable, we reduce from  $\bar{A}_{TM}$  which is known to be non-semi-decidable.

**Theorem 9.**  $\bar{A}_{TM} < INF$ .

*Proof.* Given  $\langle M, w \rangle$ , construct

$M'$ : “On input  $x$ , simulate  $M$  on  $w$  for  $|x|$  steps. If  $M$  accepts  $w$  within  $|x|$  steps, then Reject  $x$ . If  $M$  does not accept  $w$  within  $|x|$  steps, then Accept  $x$ .”

If  $M$  does not accept  $w$ , then  $M'$  will accept every  $x$ , and so  $L(M') = \Sigma^*$  is infinite.

Suppose  $M$  accept  $w$ . Then  $M$  accepts  $w$  within some  $t$  number of steps, where  $t$  is a constant dependent on  $M$  and  $w$ . We get that for every input  $x$  of length  $|x| < t$ , our simulation of  $M$  on  $w$  for  $|x|$  steps will not accept, and so  $M'$  accepts  $x$ . On the other hand, for every  $x$  of length  $|x| \geq t$ , our simulation of  $M$  on  $w$  for  $|x|$  steps will complete with success, and so  $M'$  will reject  $x$ . Note that the number of  $x$ 's that  $M'$  accepts is finite (all strings of length less than  $t$ , which is  $2^t - 1$ , a constant dependent on  $M$  and  $w$ ). So,  $L(M')$  is finite in this case.

Thus we get that  $M$  accepts  $w$  iff  $L(M')$  is finite.  $\square$

Finally, to prove that the complement of  $INF$  is not semi-decidable, we need to give a reduction from  $\bar{A}_{TM}$  to  $\overline{INF}$ . By the following easy result (Theorem 10 below), this is equivalent to giving a reduction from  $A_{TM}$  to  $INF$ . We have given such a reduction earlier (see Theorem 8)! So we're done.

**Theorem 10.** Let  $A$  and  $B$  be any two languages. We have  $A < B$  iff  $\bar{A} < \bar{B}$ .

The proof is a simple exercise!
